Introduction and Motivation

Chemical Formula

- Rubrene: 5,6,11,12-tetraphenyltetracene ($C_{42}H_{28}$)

Application

- Plastic electronics
- Organic field effect transistor (OFET)
- Organic photovoltaic devices

Mobility

- Organic semiconductor
- Single crystal rubrene: 15-20 $\text{cm}^2/\text{V s}$
- Comparable to polysilicon

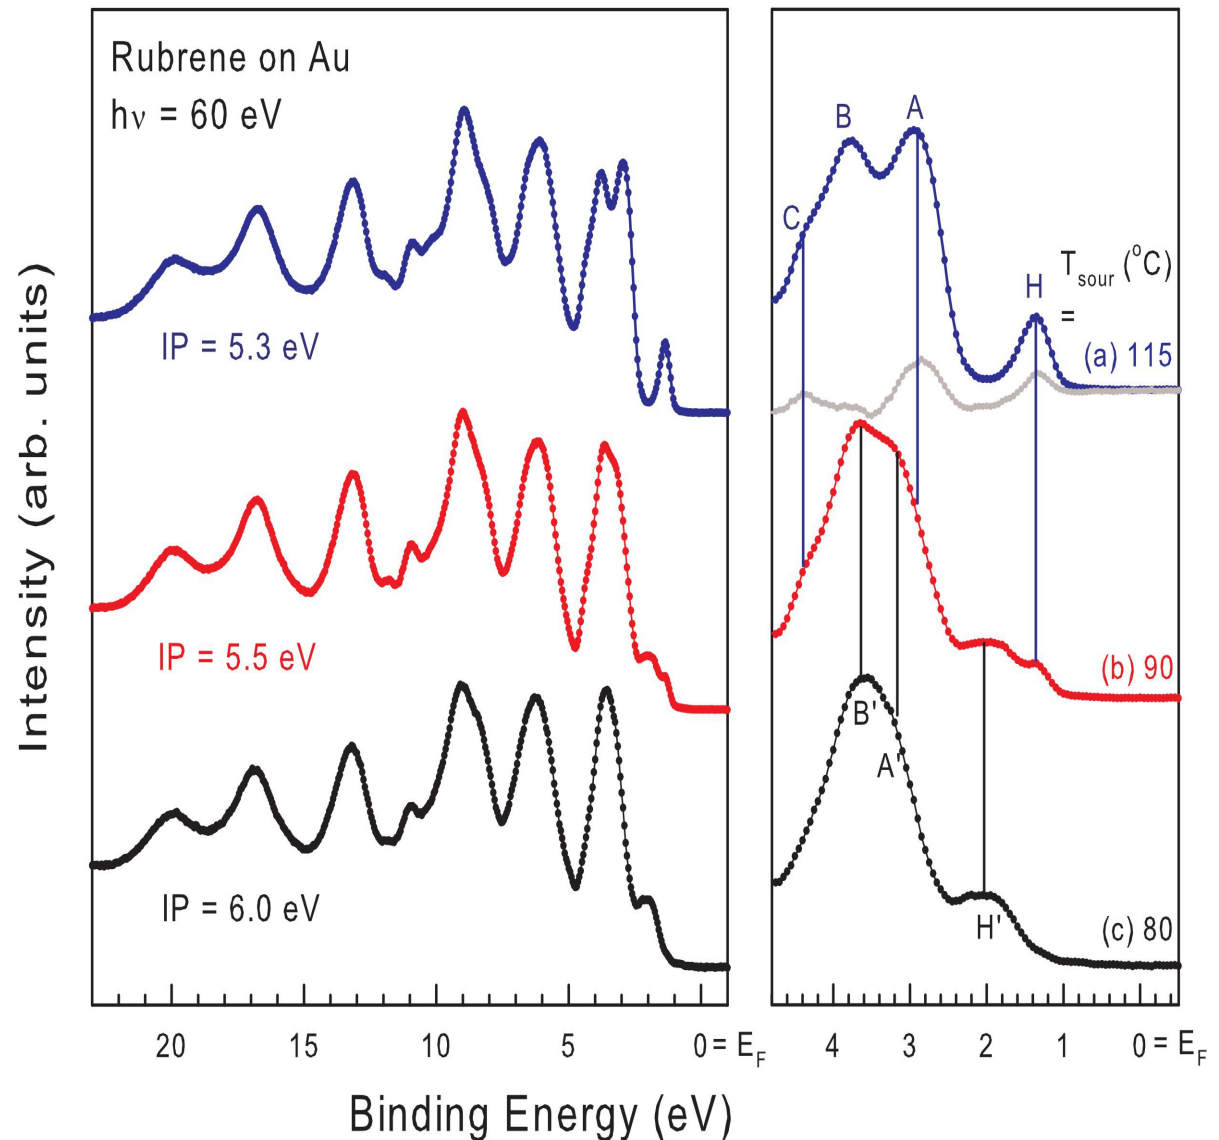

Single Crystal Rubrene

- Orthorhombic
- Pi-pi overlap along b direction → anisotropic conductivity

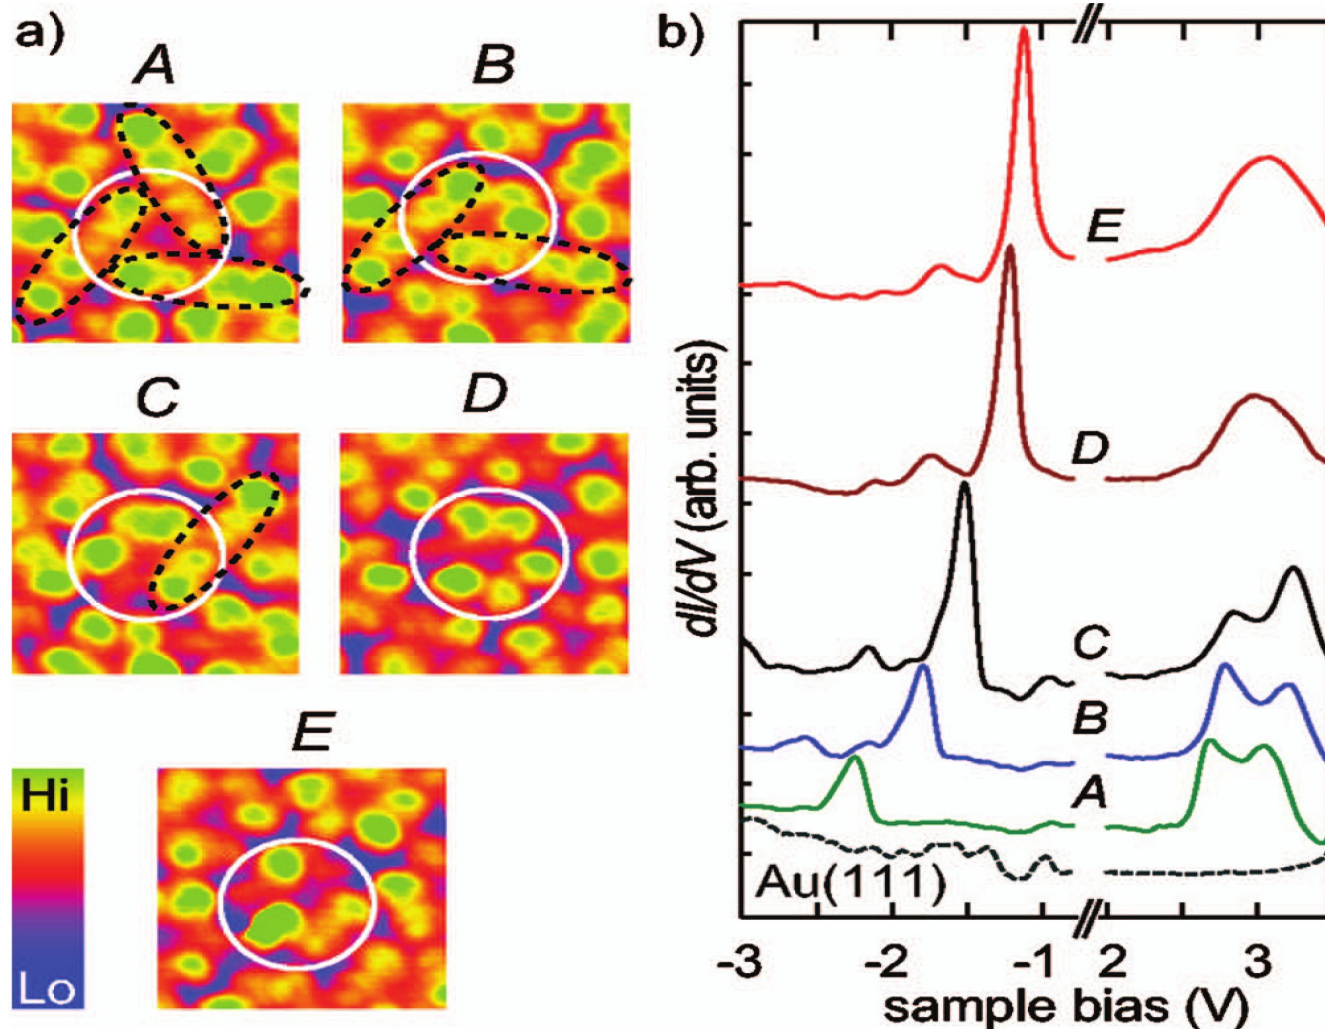

Photoemission Spectra (PES)

- Depends on temperature only
- Indep. of thickness and substrate
- HOMO:
High T(115 C) >
Low T(80 C) by
~0.8 eV
- Data obtained by Prof.
C. P. Cheng, NCYU

HOMO Shifting Observed with STM

PHYSICAL REVIEW B 73, 195409 (2006)

Conformations

- Gaseous: D_{2h} symmetry; twisted backbone (Fig. b)
- Crystalline: C_{2h} symmetry; planar backbone (Fig. c)

Results and Discussion

Simulation Package

GAMESS-US

- GAMESS-US: General Atomic and Molecular Electronic Structure System
- Quantum chemistry (HF and DFT)
- Free and Fortran source available
- Parallelized by DDI or MPI
- Can be queued by PBS Torque (and others)

Conformation Simulation

- Theory level: B3LYP/6-31G

D₂ Symmetry
(Twisted backbone;
44.4 degrees)

C_{2h} Symmetry
(Planar backbone)

Molecular Orbitals – C_{2h}

- Theory level: B3LYP/6-31G
- HOMO(Au)

LUMO(A_g)

Molecular Orbitals – D2

- Theory level: B3LYP/6-31G
- Backbone twisting ~
w.f. not much change around nuclei
- HOMO(A) LUMO(B1)

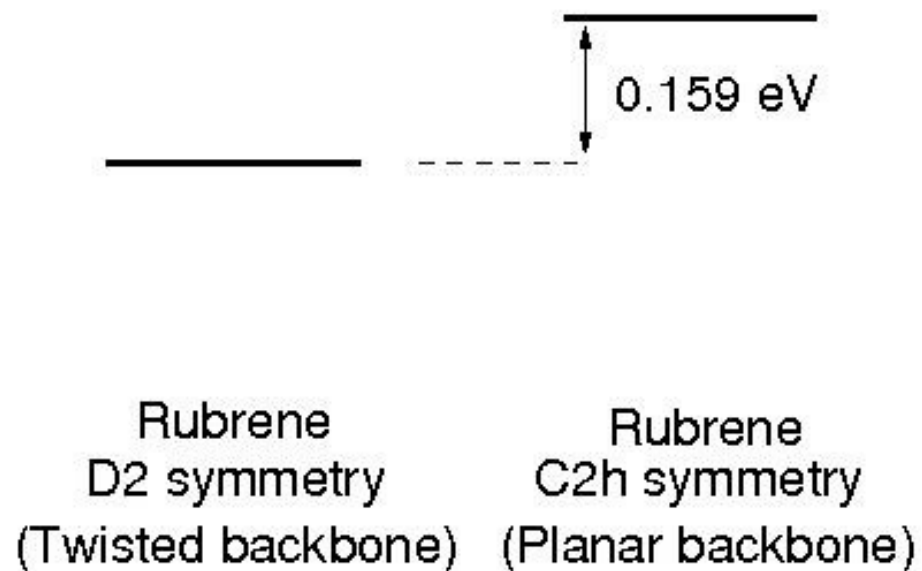

Energy and HOMO (DFT)

- Theory level: B3LYP/6-31G

Theory Level: B3LYP/6-31G

Rubrene D2 symmetry (Twisted backbone) Rubrene C2h symmetry (Planar backbone)

(a) HOMO and LUMO energies

(b) Total energies

Energy and HOMO (HF/6-31G)

- Qualitatively(or semi-quantitatively) agrees with DFT
- HOMO shift: close to DFT; one order of mag. < exp.

Theory Level: HF/6-31G

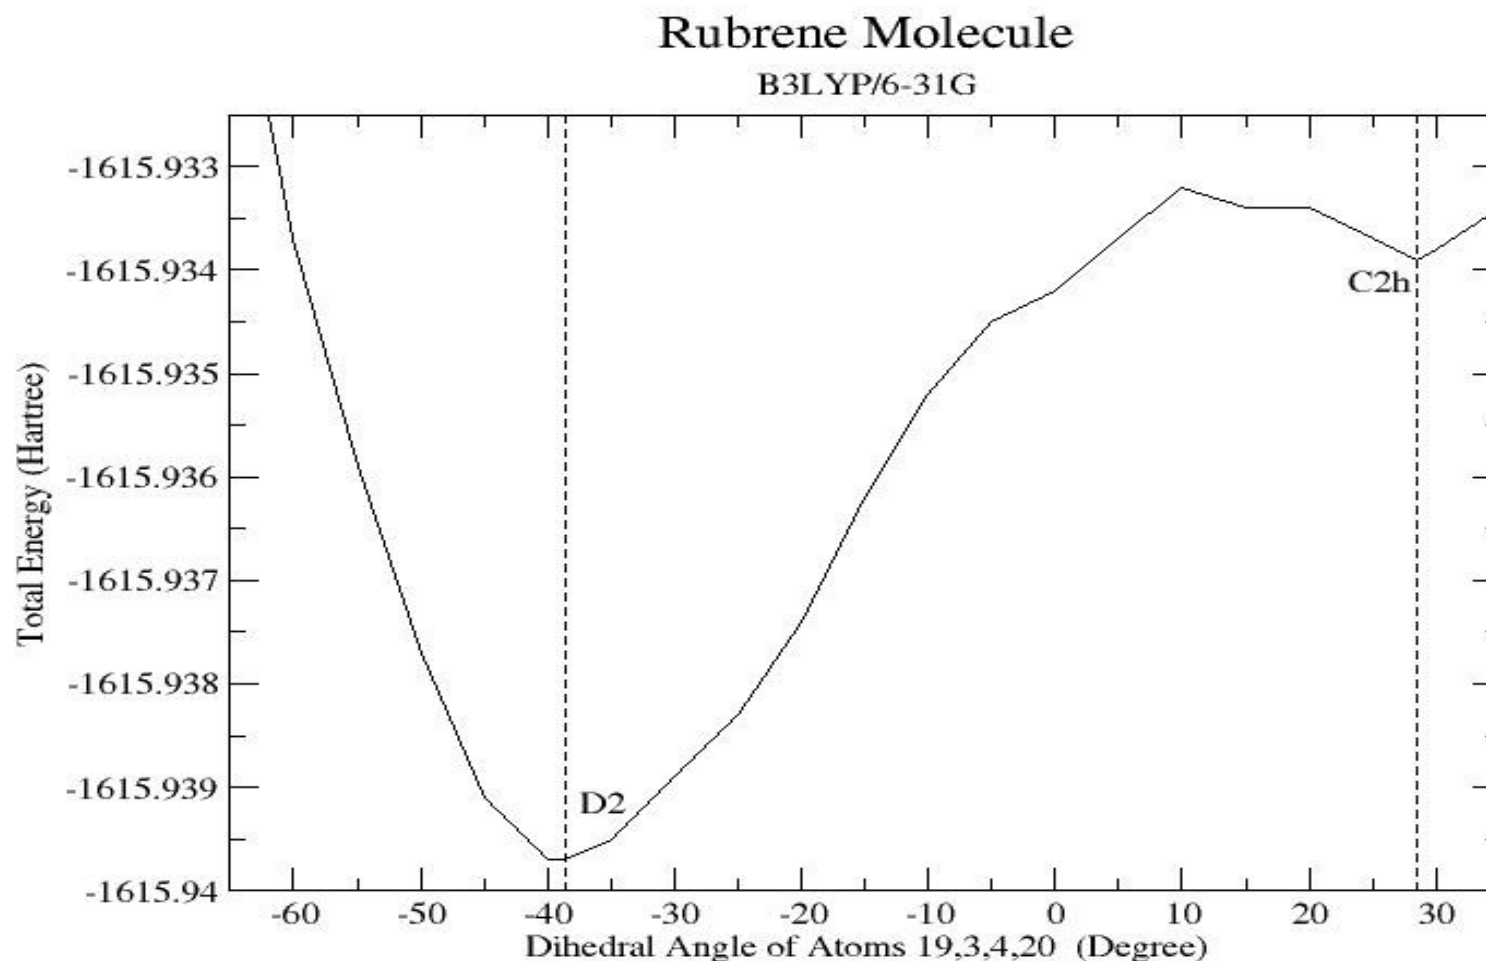

Transition – Total Energy

- Energy barriers

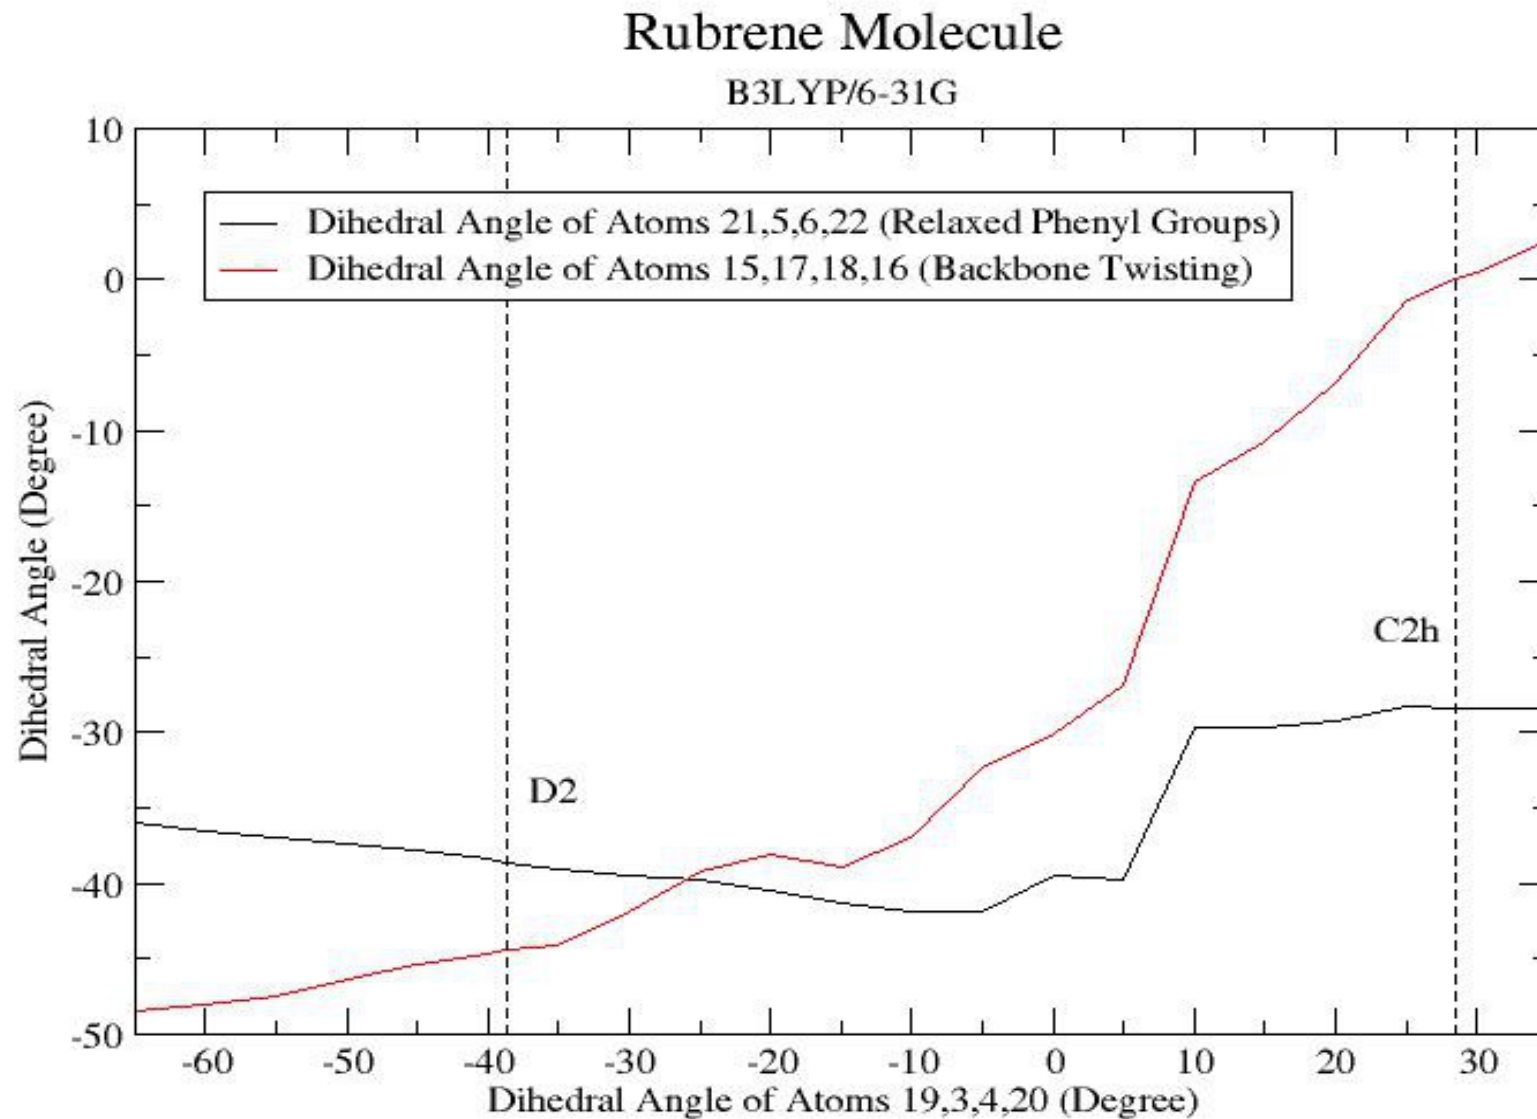

C2h \rightarrow D2 0.018 eV (209 K)

D2 \rightarrow C2h 0.177 eV (2055 K)

Transition – Geometry

- Largest twist angle adjustment near max. energy

Transition – HOMO & LUMO

- HOMO change C2h → D2: 0.08 eV << exp. (0.8eV)

Rubrene Ion (DFT) – HOMO

- $E(\text{C2h Rub}) - E(\text{D2 Ion}) = 2.737 \text{ eV} = (3\sim 4) \cdot 0.8 \text{ eV}$
- eg. Loss of 2 electrons/6-rubrene cluster

B3LYP/6-31G

Rubrene Ion (HF) – HOMO

- $E(\text{C2h Rub}) - E(\text{D2 Ion}) = 0.664 \text{ eV} \sim 0.8 \text{ eV}$

HF/6-31G

Possible Reasons to Observe Ions

- Low temperature deposition
 - Not single crystal
 - Poor conductivity
 - Sample ionization
- Can be verified by conductivity experiment

Concluding Remarks

- Energy barriers between conformations of rubrene are reported
- HOMO shift of ~ 0.8 eV can not be due to conformation, most likely due to ionized rubrene (to be checked by conductivity experiment)
- HOMO shifts predicted by DFT and HF differ by 3 times. Which to trust in?

Ongoing Work

- Present work based on 6-31G
- Need to use more complete basis sets
 - Trajectory of conformation change: 6-31+G(2d,p)
 - Molecule and ion(C_{2h} and D₂): 6-31++G(3df,3p) or aug cc-pVnZ family to extrapolate the CBS
- HF → CCSD or CCSD(T) to include correlation
- Double check PES data

Thank you for your attention.
